(57) Disclosed is a method and composition for treating ocular inflammation in a mammal in need of

such treatment, including administering to the mammal an anti-inflammatory amount of rapamycin.

**FIG. 1**

FIELD OF THE INVENTION

The present invention relates to the treatment of ocular inflammation. More particularly, the present invention relates to the treatment of ocular inflammation by administration of rapamycin.

BACKGROUND OF THE INVENTION

Ocular inflammation may take the form of numerous eye disorders of varying severity depending on the location of the inflammation. Disorders attributed to ocular inflammation include uveitis, conjunctivitis, episcleritis, scleritis, optic neuritis, retrobulbar neuritis, keratitis, blepharitis, and the like. Many of these conditions occur secondary to bacterial or viral infection.

In ocular bacterial infection, endotoxin (the lipopolysaccharide component of gram negative bacteria) produces ocular inflammation as indicated by conjunctival and iridial hyperemia, breakdown of blood aqueous barrier and polymorphonuclear neutrophil infiltration into the aqueous humor and iris ciliary body. In this type of inflammation, some of the arachidonic acid metabolites of the prostaglandins and leukotrienes have been implicated as inflammatory mediators. Other studies have also demonstrated that additional inflammation may be caused by the secondary induction of the expression of major histocompatibility complex Class II (1a) antigens in the iris ciliary body.

Ocular inflammation can also result following ophthalmologic surgical procedures or ocular trauma resulting from physical injury of the eye.

Uveitis is typical of these ocular disorders, and is characterized by inflammation of the uveal tract, which encompasses the iris, ciliary body, and choroid. Retinal inflammation is also classified as a type of uveitis. Uveitis may be anatomically classified as anterior (iritis and iridocyclitis), intermediate (cyclitis and peripheral uveitis), posterior (choroiditis and retinitis) and diffuse (iritis plus intermediate uveitis plus chorioretinitis). Merck Manual, 15th ed., 2227 (1987).

Repeated episodes of anterior uveitis, for example, can cause permanent and severe damage to the internal structures of the eye with grave consequences. For example, recurrent anterior uveitis may lead to the formation of considerable peripheral anterior synechia and secondary glaucoma. Chronic anterior uveitis can also cause corneal endothelial dysfunction and even cataract formation. Posterior inflammation can lead to persistent pathological vitreous alteration and retinal dysfunction, either of which may result in intractable visual loss.

It is well known that during acute and chronic inflammation various putative mediators of inflam-

mation are released by the inflamed tissues and by leukocytes. The concentrations of these mediators and leukocytes are indicative of the level or degree of inflammation. Likewise, a reduction in concentration of these mediators and leukocytes is an indication of the effectiveness of a drug in treating inflammation.

Anti-inflammatory steroidal preparations (e.g., corticosteroids) are currently the drug of choice in the treatment of uveitis and other ocular inflammatory conditions. Although there is a wide range of other anti-inflammatory drugs available, only corticosteroids are presently approved for use in the treatment of ocular inflammation.

The anti-inflammatory action of corticosteroids is thought to be due to interference with arachidonic acid metabolism, i.e., by inhibition of phospholipase A₂ which causes the release of arachidonic acid from the tissue phospholipid pool. Although steroids are effective in the treatment of ocular inflammation, their extended use is complicated by severe and numerous side effects. Therefore, it would be highly desirable to develop new nonsteroidal drugs which have a high therapeutic effectiveness but which do not exhibit steroid-like side effects. It has been previously demonstrated that dexamethasone (a corticosteroid), cyclosporin A (a potent immunosuppressive agent) and rapamycin (an antifungal and immunosuppressive agent) inhibited the corneal graft rejection process in the heterolammellar corneal transplantation model in the rabbit. Current Eye Res., 9:749-757 (1990). In this study, rapamycin was also found to be more potent than cyclosporin A in prolonging the graft survival after cessation of treatment.

Some preliminary clinical studies demonstrated that cyclosporin A may be effective in alleviating inflammatory symptoms in chronic idiopathic uveitis patients, some of whom were resistant to corticosteroid treatment. Am. J. Ophtal., 96:275-282 (1983); Lancet, 2:235-238 (1983). However, numerous cytotoxic side effects are observed with cyclosporin A, most likely due to the large doses of cyclosporin A required to obtain a therapeutic effect.

Accordingly, it is desirable to develop a treatment for ocular inflammation without the deleterious side effects of corticosteroids or cyclosporin A.

Rapamycin, a macrocyclic triene antibiotic produced by Streptomyces hygroscopicus, and described in U.S. Patent 3,929,992, incorporated herein by reference, has been shown to prevent the formation of humoral (IgE-like) antibodies in response to an albumin allergic challenge [Martel, R., Can. J. Physiol. Pharm. 55:48 (1977)], inhibit murine T-cell activation [Strauch, M., FASEB

3:3411 (1989)], and prolong survival time of organ grafts in histoincompatible rodents [Morris, R., Med. Sci. Res. 17:877 (1989)].

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a bar graph showing the change in level of leukocytes in aqueous humor after various treatments with dexamethasone, cyclosporin A and rapamycin, compared with controls.

Figure 2 is a bar graph showing the change in level of protein in aqueous humor after various treatments with dexamethasone, cyclosporin A and rapamycin, compared with controls.

Figures 3A and 3B are bar graphs showing the change in levels of PGE₂ and LTB₄, in aqueous humor, respectively after various treatments with dexamethasone, cyclosporin A and rapamycin, compared with controls.

Figures 4A and 4B are bar graphs showing the change in levels of iris-ciliary body PGE₂ and iris-ciliary body LTB₄, respectively after various treatments with dexamethasone, cyclosporin A and rapamycin, compared with controls.

Figure 5 is a bar graph showing the change in levels of iris-ciliary MPO activity after various treatments with dexamethasone, cyclosporin A and rapamycin, compared with controls.

SUMMARY OF THE INVENTION

The present invention is directed to a method of treating ocular inflammation in a mammal in need of such treatment, including the administration of an anti-inflammatory amount of rapamycin to the mammal.

DESCRIPTION OF THE INVENTION

The present invention is directed to the treatment of ocular inflammation by the administration of an anti-inflammatory amount of rapamycin. The rapamycin may be administered by any suitable means, including: oral, parenteral, topical, transdermal, rectal, intravenous, intramuscular, intraocular, intravitreal and subcutaneous administration.

In particular, rapamycin is useful in providing symptomatic relief of, preventing the progression of, or eradicating ocular inflammation, associated with, resulting from, or described as, for example, uveitis, conjunctivitis, episcleritis, scleritis, optic neuritis, retrobulbar neuritis, keratitis, blepharitis, and the like; ocular inflammation following ocular surgery; and ocular inflammation resulting from physical eye trauma.

Several standard pharmacological ocular inflammatory models have been used to study anti-inflammatory effects of steroidal and non-steroidal

drugs. These include: (1) endotoxin-induced uveitis which is an acute and non-immunogenic model; (2) uveitis induced by bovine serum albumin, which is an immunogenic model; (3) corneal injury model [Kulkarni, P.S., Trends in Pharmacol Sci 8 (10); (1987)]; and (4) corneal heterolamellar transplant model (Guo, A., Curr. Eye Res. 9 (8) : 749 (1990)).

The effect of rapamycin on ocular inflammation was established in an *in vivo* experiment using the endotoxin-induced uveitis model, which emulates inflammatory eye disorders observed in mammals. The procedure used and results obtained are described below.

EXAMPLE 1

The following experiment demonstrates the effect of dexamethasone, cyclosporin A and rapamycin on endotoxin-induced uveitis in rabbits.

Thirty-two New Zealand male rabbits weighing between 1.5 and 2.0 kg. were used in this study. The rabbits were divided into four groups according to drug treatment. The rabbits were treated according to the guidelines of the use of animal in research by the Association of Research in Vision and Ophthalmology (ARVO) resolution.

Each of the groups was compared to its own vehicle-treated control group, as the grade of uveitis is known to vary from one experiment to another. All rabbits were pre-treated with their respective drugs one hour before intravitreal injection of endotoxin.

E. coli endotoxin (LPS) obtained from Sigma Co. (St. Louis, Missouri) was dissolved in sterile physiological saline solution at a concentration of 10ng./μl. After cleansing and anesthetizing each eye of the rabbit with topical alaine (proparacaine HCL) 10μl (100ng) of the LPS was injected intravitreally (using a 30G needle attached to a Hamilton constant range syringe) into both eyes of each rabbit. All the rabbits were euthanized with an overdose of Pentobarbital Sodium (euthanasia strength) 24 hours after the LPS injection, by which time maximal inflammation has occurred. Trends in Pharmacological Sciences, 8:375-377 (1987).

Aqueous humor was obtained immediately by paracentesis using a 22 gauge needle containing 50μl of heparinized saline. The aqueous humor from both eyes of each rabbit was pooled. The eyes were then enucleated, sectioned around the equator and the iris ciliary body was gently lifted out and divided for radioimmunoassay (RIA) and myeloperoxidase (MPO) assay. The iris ciliary bodies from both eyes of each rabbit were also pooled for the RIA and MPO assays. Cell count, protein determination as well as PGE₂ and LTB₄ levels were determined from the aqueous humor while PGE₂ and LTB₄ synthesis and MPO activity were

determined from iris ciliary bodies. In each group, the number of samples for each of the assayed mediator as well as for the cell count and protein determination was four.

Drugs and Treatment Regimen

The rabbits were divided into four groups according to drug treatment as follows:

- GROUP I: Control - Topical 0.9% sterile saline every four hours.
Experimental - Topical dexamethasone (0.1%) every four hours.
- GROUP II: Control - intramuscular injection (I.M.) 0.9% Saline t.i.d.
Experimental - I.M. dexamethasone (2mg/kg) t.i.d.
- GROUP III: Control - I.M. Castor Oil b.i.d.
Experimental - I.M. cyclosporin A (25mg/kg) b.i.d.
- GROUP IV: Control - I.M. Carboxymethyl Cellulose (CMC)
Experimental - I.M. rapamycin (10mg/kg. b.i.d.

Absolute values of treatment and control groups were respectively compared using student's unpaired t-test for statistical evaluation.

Dexamethasone was dissolved in sterile physiological saline (0.9%) while cyclosporin A was suspended in castor oil. rapamycin was suspended in carboxymethyl cellulose. All rabbits were given the first dose of their respective drug treatments one hour before intravitreal endotoxin injection and the last dose one hour before euthanasia. The topical dexamethasone group received four additional treatments at four-hour intervals between the first and last treatments. The I.M. dexamethasone group received one more treatment between the first and last while the I.M. cyclosporin A and rapamycin groups received just the first and last treatments only. All I.M. injections were given in the rabbit thigh muscle.

Leukocyte Count

The aqueous humor leukocytes were counted by mixing 5μl of the aqueous humor (obtained by a precision microsyringe - Hamilton Co., Reno, Nevada) with 5μl of Turk's solution (dilute glacial acetic acid + gentian violet) and placing this mixture on a hemocytometer. The cells were counted using a light microscope.

Protein Determination

The protein concentration of the aqueous humor was measured using 5μl of the aqueous hu-

mor. BioRad protein assay (BioRad Labs, Richmond, CA) was used to determine the protein concentration. BioRad assay is based on the shift of absorbance of Coomassie Brilliant Blue G-250 from 465-595nm when binding to protein occurs. Absorbance was read using a Beckman DU64 Spectrophotometer.

Measurement of the Release of PGE₂ and LTB₄ into Aqueous Humor

The concentration of these eicosanoids (biologically active substances derived from arachidonic acid) in the aqueous humor and the incubated iris ciliary body was measured using the respective radioimmunoassay (RIA) Kits (Amersham, Arlington Hts., IL). The eicosanoids were extracted from acidified (pH 3) aqueous humor samples in chloroform: Methanol (2:1) mixture. The organic phase was dried under nitrogen (N₂) and the samples were reconstituted in the buffer provided in the RIA kits.

Measurement of PGE₂ and LTB₄ Synthesis in Iris Ciliary Body

The MPO activity in the iris ciliary body was measured according to the method elaborated by Bradley. J. Invest. Dermatoloy, 78:207-209. In this method, the enzyme (MPO) found in the intracellular granules of neutrophils is utilized as a marker for tissue neutrophil content.

Aqueous Humor Leukocyte Content

The effect of the different drug treatments on aqueous humor inflammatory cells is represented in Fig. 1. I.M. dexamethasone produced a highly significant (P < 0.05) reduction (72%) in the aqueous humor leukocyte as compared with its control group, while topical dexamethasone caused only a 17% decrease in counts. cyclosporin A I.M. reduced the leukocyte counts by 36% while I.M. rapamycin caused a highly significant decrease (77%) in aqueous humor leukocyte.

Aqueous Humor Protein

Fig. 2 shows the effect of the drugs on aqueous humor protein concentration. None of the drug treatments significantly reduced the aqueous humor protein concentration (P > 0.05). I.M. dexamethasone and topical dexamethasone reduced the aqueous humor protein content by 31% and 24%, respectively. I.M. rapamycin decreased the protein level by 22% while I.M. cyclosporin A did not seem to affect the protein level considerably, with only a 4% reduction.

Inflammatory Mediators

Figures 3 and 4 illustrate the effect of drug treatment on the release of PGE₂ and LTB₄ into aqueous humor and their synthesis in iris ciliary body. I.M. dexamethasone significantly ($P < 0.05$) inhibited the PGE₂ release into the aqueous humor and iris ciliary body by 54% and 47%, respectively. It did not, however, have a significant effect on the LTB₄ levels with an inhibition of only 30% in the aqueous humor. The synthesis of LTB₄ in iris ciliary body was not affected by I.M. dexamethasone. Topical dexamethasone had a large effect ($P < 0.05$) on the aqueous humor eicosanoid levels. It caused an inhibition of 89% (PGE₂) and 67% LTB₄ in the aqueous humor. It had no significant effect on the eicosanoid levels in the iris ciliary body. I.M. rapamycin significantly decreased the release of PGE₂ into the aqueous humor by 61% while decreasing the aqueous humor LTB₄ by 30%. Rapamycin did not affect the eicosanoid levels in the iris ciliary body. Also, I.M. cyclosporin A did not have any significant effect ($P > 0.05$) on the aqueous humor eicosanoid levels. In the iris ciliary body, it reduced PGE₂ levels by 30% and the LTB₄ level by only 7%.

Myeloperoxidase Activity

Fig. 5 represents the polymorphonuclear neutrophil infiltration into the iris ciliary body as indicated by the myeloperoxidase activity. I.M. dexamethasone, I.M. cyclosporin A and I.M. rapamycin significantly ($P < 0.05$) decreased the MPO activity in the iris ciliary body by 73%, 69% and 63%, respectively, while topical dexamethasone reduced the iris ciliary body-MPO activity by only 30%.

In the present study, despite more frequent doses, topical dexamethasone did not significantly affect the leukocyte count in the aqueous humor. However, it significantly inhibited the release of LTB₄ into the aqueous humor but not its synthesis in the iris ciliary body (iris ciliary body). The aqueous humor protein as well as myeloperoxidase (MPO) activity in the iris ciliary body were not significantly inhibited by topical dexamethasone. However, I.M. dexamethasone significantly inhibited leukocyte infiltration into the aqueous humor. The aqueous humor protein concentration was lowered, but not significantly. PGE₂ release into the aqueous humor and its synthesis by the iris ciliary body were significantly inhibited by I.M. dexamethasone, while the LTB₄ levels in both the aqueous humor and iris ciliary body were not affected.

Rapamycin and cyclosporin A were both effective in decreasing the leukocyte response in the aqueous humor. The leukocyte counts in the cyclosporin A group were much lower than those in

the other groups. This is probably due to the vehicle (castor oil) that was used. Castor oil is believed to have a mild anti-inflammatory effect in the eyes of animals after removal of a foreign body from the eye. The Merck Index, 8th Edition. Rapamycin and cyclosporin A did not significantly lower the protein content of the aqueous humor nor did they affect the eicosanoid synthesis in the iris ciliary body. The overall anti-inflammatory effect of rapamycin and cyclosporin A was less than that of dexamethasone in this model. However, in this study rapamycin was at least three times more effective than cyclosporin A. Rapamycin has also been found to be three to fifty times more effective than cyclosporin A in inhibiting the graft rejection process in heterotrophic heart, skin and kidney models. Transplantation and Immunology Letter, VII:5-7 (1990). In summary, rapamycin (10 mg/kg bid) given intramuscularly inhibited aqueous humor leukocytes by 67%, PGE₂ by 75%, and myeloperoxidase activity in the iris ciliary body by 50%. Cyclosporin A (25 mg/kg bid, intramuscularly) inhibited aqueous humor leukocytes by 36%, iris ciliary body PGE₂ by 30%, and myeloperoxidase activity 68%. These results show that rapamycin is useful in preventing or treating inflammatory ocular disorders.

When rapamycin is employed in the treatment of inflammatory ocular disorders, it can be formulated neat or with a pharmaceutical carrier to a mammal in need thereof. The pharmaceutical carrier may be solid or liquid.

A solid carrier can include one or more substances which may also act as flavoring agents, lubricants, solubilizers, suspending agents, fillers, glidants, compression aids, binders or table-disintegrating agents; it can also be an encapsulating material. In powders, the carrier is a finely divided solid which is in admixture with the finely divided active ingredient. In tablets, the active ingredient is mixed with a carrier having the necessary compression properties in suitable proportions and compacted in the shape and size desired. The powders and tablets preferably contain up to 99% of the active ingredient. Suitable solid carriers include, for example, calcium phosphate, magnesium stearate, talc, sugars, lactose, dextrin, starch, gelatin, cellulose, methyl cellulose, sodium carboxymethyl cellulose, polyvinylpyrrolidone, low melting waxes and ion exchange resins. Liquid carriers are used in preparing solutions, suspensions, emulsions, syrups, elixirs and pressurized compositions. The active ingredient can be dissolved or suspended in a pharmaceutically acceptable liquid carrier such as water, an organic solvent, a mixture of both or pharmaceutically acceptable oils or fats. The liquid carrier can contain other suitable pharmaceutical additives such as solubilizers, emulsifi-
